#### Lecture 6 — Inter-Process Communication

Jeff Zarnett jzarnett@uwaterloo.ca

Department of Electrical and Computer Engineering University of Waterloo

August 29, 2021

ECE 252 Fall 2021 1/56

#### **IPC Motivation**

When 2+ processes would like to co-ordinate/exchange data the mechanism is called inter-process communication.

If a process shares data with another process in the system, the operating system will provide some facilities to make this possible.

The motivations for inter-process communication are fairly obvious.

ECE 252 Fall 2021 2 / 56

#### **IPC Preliminaries**

Before proceeding, we need to define some things.

It is the transfer of data from one process to another.

The data being transferred is typically referred to as the *message*.

The process sending that message is the sender.

The process receiving it will be the receiver.

This terminology may seem (painfully) obvious.

ECE 252 Fall 2021 3/56

ECE 252 Fall 2021 4/56

#### **IPC: What to Send**

The processes involved must have some agreement on: What data a message should contain; and The way the data is formatted.

There may be defined standards, e.g., XML.

The processes themselves must be aware the message is in XML format.

How this agreement is made falls outside the purview of the OS.

ECE 252 Fall 2021 5/56

#### Messages: (A)synchronous

Sending and receiving of messages may be either synchronous or asynchronous.

Synchronous Send: the sender sends the message and then is blocked from proceeding until the message is received.

Asynchronous Send: the sender can post the message and then carry on.

Synchronous Receive: the receiver is blocked until it receives a message.

Asynchronous Receive: the receiver is notified there is no message available and continues execution.

ECE 252 Fall 2021 6/5

#### Messages: (A)synchronous

Thus there are four combinations to consider, three of which are common:

- 1 Synchronous send, synchronous receive
- 2 Synchronous send, asynchronous receive
- 3 Asynchronous send, synchronous receive
- 4 Asynchronous send, asynchronous receive

We may also have "acknowledgement" messages.

ECE 252 Fall 2021 7/56

#### **Producer-Consumer Problem**

A general paradigm for understanding IPC is known as the *producer-consumer* problem.

The producer creates some information.

The information is later used by the consumer.

Example: the database produces data to be consumed by the shell.

This is a general problem and applicable to client-server situations.

ECE 252 Fall 2021 8 / 56

## **IPC Implementation Strategies**

There are three approaches we will consider on how we can accomplish IPC:

- 1 Shared memory.
- 2 The file system.
- Message passing.

All are quite common.

ECE 252 Fall 2021 9 / 56

ECE 252 Fall 2021 10 / 56

Conceptually, the idea of shared memory is very simple.

A region of memory is designated as being shared with some processes.

Those processes may read and write to that location.

To share an area of memory, the OS must be notified.

ECE 252 Fall 2021 11/56

Normally, a region of memory is associated with exactly one process (its owner).

That process may read and write that location.

Other processes may not.

If a second process attempts to do so, the operating system will intervene and that will be an error.

If a process wants to designate memory as shared, it needs to tell the operating system it is okay.

ECE 252 Fall 2021 12 / 5

The OS needs to know that the memory is referenced by two processes.

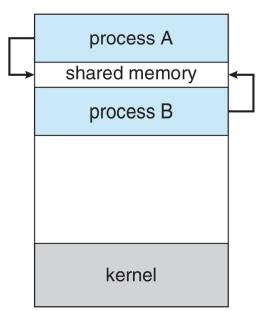

If the first one terminates and is reaped, the memory may still be in use by the second process.

The previously-shared region should not be considered free as long as the second process is still using it.

Once the area of memory is shared, when either process attempts to access it, it is just a normal memory access.

The kernel is only involved in the setup and cleanup of that shared area.

ECE 252 Fall 2021 13 / 5

ECE 252 Fall 2021 14/56

## Shared Memory: Risk

When a section of memory is shared, there is the possibility that one process overwrites another's changes.

To prevent this, we need a system of co-ordination.

... A subject we will return to later.

ECE 252 Fall 2021 15/56

## File System

ECE 252 Fall 2021 16 / 56

Another way for 2 processes to communicate is through the file system.

Unlike shared memory, messages stored in the file system are persistent.

Can be used if the sender & receiver know nothing about one another.

ECE 252 Fall 2021 17/56

The producer may write to a file in an agreed upon location.

The consumer may read from that same location.

The operating system is still involved because of its role in file creation and manipulation.

ECE 252 Fall 2021 18 / 56

#### File System: Co-ordination

If one file is being used then we still have the problem of co-ordination.

We can get around this, however, by using multiple files with unique IDs.

Example from a co-op work term: if the producer is generating XML data, it can write in a file in a designated import/ directory.

The consumer program scans the directory, and imports files.

In this case, since one process writes files and another reads them, there is no possibility that one process overwrites the data of another.

If the sender chooses distinct file names, it will not overwrite a message if a second message is created before the receiver picks up the first.

ECE 252 Fall 2021 19 / 56

## Message Passing

ECE 252 Fall 2021 20 / 56

#### **Message Passing**

Message passing is a service provided by the operating system.

The sender will give the message to the OS and ask that it be delivered to a recipient.

There are two basic operations: sending and receiving.

Messages can be of fixed or variable size.

ECE 252 Fall 2021 21/56

#### **Message Passing**

Our experience with postal mail, or e-mail, suggests that to send a message successfully, the sender needs to indicate where the message should go.

Under *direct communication*, each process that wants to communicate needs to explicitly name the recipient or sender of the communication.

We have to know some identifier for the other processes; not very flexible.

ECE 252 Fall 2021 22/56

Signals are interrupts with a specified ID.

Image Credit: Steven Puetzer/Getty Images

They don't really contain a message.

ECE 252 Fall 2021 23 / 56

#### Signal: No Message

The fact that a signal contains no message is a limitation that means signals can't be used for every single interprocess communication scenario.

When the fire alarm sounds in a building, you don't need an accompanying voice announcement!

Why?

ECE 252 Fall 2021 24/56

#### Signal: Preparation

You have previously been informed that when the fire alarm sounds it means you need to exit the building.

Signals: you need to know what to listen for and what's supposed to happen if you want to react accordingly.

ECE 252 Fall 2021 25/56

### **Programmatic Signals**

The appropriate header for including signals is signal.h.

It contains the definitions that let you write SIGKILL instead of having to put an explicit int 9.

Unfortunately there is not always 100% agreement between different implementations about what the higher signal numbers mean.

ECE 252 Fall 2021 26 / 56

#### **Programmatic Signals**

There are two functions for sending a signal programmatically:

```
int kill( int pid, int signo );
int raise( int signo );
```

Both functions return 0 if they were successful and -1 if they were unsuccessful.

The raise function sends the signal to the current process.

ECE 252 Fall 2021 27/56

### Finding the Identity of a Stranger

We need to know the process ID of the recipient.

But how do processes find one another's IDs? Registration!

mysql (a database) server will put its process ID in the file /var/run/mysqld/mysqld.pid.

In that file is just the number of its process ID (e.g., 1494).

Any other communication method will work!

ECE 252 Fall 2021 28 / 56

## Why not Function Overload?!

The kill function does different things depending on its first argument.

- pid > 0
- pid == 0
- pid == -1
- pid < -1

ECE 252 Fall 2021 29 / 56

## The Null Signal

You can also invoke the kill function with a O argument for the signal.

This is called the null signal.

It does not actually send any signal, but can be used to check if the recipient process exists.

But beware: process IDs are only relatively unique!

ECE 252 Fall 2021 30 / 56

#### Did You Get My Text?!

A process can only actually deal with a signal when that process is running.

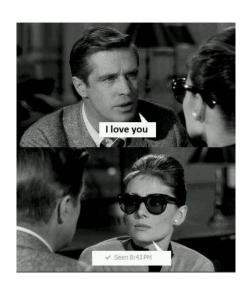

A signal is generated by something, and it is later delivered to the recipient.

But during the time between generation and delivery, we say the signal is pending.

It will be delivered at the first opportunity.

ECE 252 Fall 2021 31/56

### Awk-ward!

ECE 252 Fall 2021 32 / 56

#### Refuse to Listen

For most (but not all) signals, your process can choose to refuse to listen.

This is called blocking signals, and can be done to any with with the exception of SIGKILL and SIGSTOP.

When a signal is blocked, it just remains in the pending state until signals of that type are unblocked.

Blocking is meant to be temporary.

ECE 252 Fall 2021 33 / 56

### **Signal Default Actions**

Signals have a default action.

The action taken when the signal is delivered is the disposition of the signal.

If you don't explicitly change what happens when the signal arrives, the default (see the table) happens.

But we can change it.

ECE 252 Fall 2021 34 / 56

## **Signal Choices**

Option 1: Ignore it.

Option 2: Run a signal handler.

Option 3: Run the default option.

We will focus on Option 2 here.

ECE 252 Fall 2021 35 / 56

#### MANY WHELPS! HANDLE IT!

If we decide to register a signal handler, the function is:

```
void (*signal( int signo, void (*handler)(int))) (int);
```

signo: Signal number to watch for

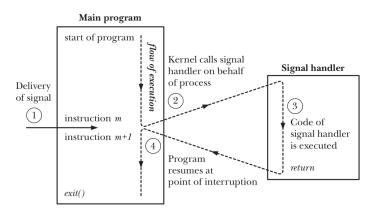

handler: Function to run to handle the signal.

So a sample signal handler would be:

```
void sig_handler( int signal_num ) {
  /* Handle the signal in some way */
}
```

ECE 252 Fall 2021 36 / 56

# Signal Handler Workflow

ECE 252 Fall 2021 37/56

## **Tread Carefully!**

The content of your signal handler, however, is restricted.

Because the handler deals with an interrupt and runs between two instructions it is important to make sure that the signal handler doesn't mess anything up.

If the signal handler runs in the middle of malloc and the signal handler itself calls malloc it could put the memory management in an invalid state!

We can only use functions that are reentrant.

ECE 252 Fall 2021 38 / 56

#### Do Some Research

There are tables of what functions are safe to invoke from within a signal handler.

In general what you are looking for is a designation of async-signal safe.

ECE 252 Fall 2021 39 / 56

To block a signal, unblock one, or just find out what the current state is, the function is:

```
int sigprocmask( int how, const sigset_t * set, sigset_t * old_set );
```

The first argument says what we're trying to do here: SIG\_BLOCK, SIG\_UNBLOCK, SIG\_SETMASK.

Third argument: updated to the old values (if provided).

ECE 252 Fall 2021 40 / 56

#### I am the Mask you wear...

#### There are some helper functions to fill in the mask:

```
int sigemptyset( sigset_t *set ); /* Initialize an empty sigset_t */
int sigaddset( sigset_t *set, int signal ); /* Add specified signal to set */
int sigfillset( sigset_t *set ); /* Add ALL signals to set */
int sigdelset( sigset_t *set, int signal ); /* Remove specified signal from set */
int signismember( sigset_t *set, int signal ); /* Returns 1 if true, 0 if false */
```

ECE 252 Fall 2021 41/56

### Signal Blocking Example

```
sigset_t set;
sigset_t previous;
sigset_t previous;
sigemptyset( &set ); /* Initialize set */
sigaddset( &set, SIGINT ); /* Add SIGINT to it */
sigprocmask( SIG_BLOCK, &set, &previous ); /* Add SIGINT to the mask */
/* SIGINT is blocked in this section */
sigprocmask( SIG_SETMASK, &previous, NULL ); /* Restore previous mask */
```

ECE 252 Fall 2021 42 / 56

# Waiting for a Page

If you want to pause your program for a bit until the call is interrupted by a signal, there is the function  $int\ pause(\ )$ .

This function always returns -1 and it suspends your program until the signal handler runs.

This can be useful if we really do need to wait for something...

ECE 252 Fall 2021 43 / 56

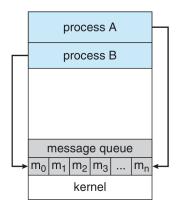

# Pass Your Message.

ECE 252 Fall 2021 44/56

### That... Did Not Help

To deal with the process ID problem, what we would like is indirect communication where the messages are sent to mailboxes (queues).

ECE 252 Fall 2021 45 / 56

## **UNIX Message Passing**

UNIX gives us this: message queues.

The max sizes and numbers of queues are implementation-specific.

In a real implementation, limits are something you need to consider:

- 1 Wait for the space to be available (block).
- Overwrite older messages (sometimes this is what you want).
- 3 Discard the current message (leave the old ones as they are).

ECE 252 Fall 2021 46 / 56

The first step in message-passing is to get a key that identifies a specific queue.

Keys are just integer values, so we would like them to be unique (or close to it).

One method is to generate the key with the "file to key" function found in sys/ipc.h:

```
key_{-}t ftok( char *pathname, int proj );
```

The file does have to exist.

ECE 252 Fall 2021 47 / 56

# Keep it Secret, Keep it Safe

Another way we can get a key is using the constant IPC\_PRIVATE.

If we give the constant in where a key\_t is expected then a guaranteed unique key is returned.

This method is used when there is a parent and child relationship between the processes that want to communicate.

ECE 252 Fall 2021 48 / 56

#### Get the Queue

Regardless of how we generate the key, we use it to get the queue with the function:

```
int msgget( key_t key, int flag );
```

key: the key we have generated or IPC\_PRIVATE.

flag: UNIX permissions, optionally IPC\_CREAT with IPC\_EXCL.

The permissions follow the UNIX permission standards, e.g. 0600.

IPC\_CREAT: create queue (if does not exist).

IPC\_EXCL: fail if trying to create and queue already exists.

Returns: the queue ID.

ECE 252 Fall 2021 49 / 56

# What does a message look like?

Unlike in a lot of other contexts, here, the message has a defined structure:

```
struct msgbuf {
    long mtype;
    char mtext[1];
};
```

ECE 252 Fall 2021 50 / 56

Whatever message type you want to send has to have the first part be a long value; anything is fine after that.

```
struct pirate_msgbuf {
    long mtype;     /* must be positive */
    struct pirate_info {
        char name[30];
        char ship_type;
        int notoriety;
        int cruelty;
        int booty_value;
    } info;
};
```

ECE 252 Fall 2021 51/56

## **Sending Data**

int msgsnd( int msqid, const void \*ptr, size\_t nbytes, int flag );

msgid: queue ID.

ptr: message to send.

nbytes: size of the message.

flag: O for blocking, IPC\_NOWAIT for return with error if queue full.

ECE 252 Fall 2021 52 / 56

#### **Receiving Data**

```
ssize_t msgrcv( int msqid, void *ptr, size_t nbytes, long type, int flag );
```

msgid: queue ID.

ptr: where the message will go.

nbytes: size of the message.

type: kind of message you want.

flag: O for blocking, IPC\_NOWAIT for return with error if queue empty.

ECE 252 Fall 2021 53 / 56

# **Type Options**

- type == 0
- **■** type > 0
- type < 0

ECE 252 Fall 2021 54/56

int msgctl( int msgid, int command, struct msgid\_ds \* buf );

msgid: queue ID.

command: IPC\_RMID to delete the queue.

buf: use NULL.

This immediately deletes the queue and all messages inside!

ECE 252 Fall 2021 55/56

## **Example of Message Passing**

```
struct msq {
  long mtype:
  int data;
}:
int main( int argc, char** argv ) {
    int msgqid = msgget( IPC_PRIVATE, 0666 | IPC_CREAT );
    int pid = fork():
    if ( pid > 0 ) { /* Parent */
        struct msq m;
       m.mtvpe = 42:
       m.data = 252;
       msgsnd( msggid, &m, sizeof( struct msg ), O );
    } else if ( pid == 0 ) { /* Child */
       struct msq m2;
       msgrcv( msgqid, &m2, sizeof( struct msq ), 42, 0 );
       printf("Received_%d!\n", m2.data );
       msqctl( msqqid, IPC_RMID, NULL );
    return 0:
```

ECE 252 Fall 2021 56/56
